A NEW SUBSPECIES OF THE RUFCUS SWAMP WARRLER ACROCEPHALUS RUFESCENS FROM SENEGAL

by P. R. Colston and G. J. Morel

Received 21 January 1985

At Lake Guiers near Pichard-Toll, Senegal, Acrocephalus rufescens occurs in the same kind of Typha beds as the African Peed Warbler A. basticatus, which has recently been found to be racially distinct (Colston & Morel 1984). In the past, efforts to describe this most northwestern population of rufescens have suffered from a lack of comparative material (Morel & Roux 1962). In order to establish the identity of these birds GUM was able to collect single adult females in April and December 1983 and five adult males in April 1984. The specimens were subsequently forwarded to the British Museum (Natural History) (RNNH) for appraisal. PRC, who examined the series, confirmed that the birds were greyer-brown, less rufous above than nominate rufescens and whiter below than any of the forecoing races in Africa, rufescens, chadensis, niloticus, foxi or ansorgei and represent a distinct form, for which we provide the name

Acrocephalus rufescens senegalensis subsp. nov.

Holotype Adult female (in fresh plumage); Lake Quiers, near Richard-Toll, Seneral, 16^25'N, 15^42'N, 10 December 1983. Collected by Dr G.J. Morel, collectors number 10-2758. Lodged in the British Museum (Natural History), Tring, RM. No. 1984-6-1.

Description When compared with nominate rufescens (southern Nigeria to northern Angola) the upperparts are greyer-brown, less rufous in appearance and there is a distinct greyish cast to the head and nape. The ear-coverts, sides of the head and neck are paler ash-brown and the lores are whiter. The underparts are also very pallid looking by comparison, even whiter than the palest race chadensis. The chin and throat are pure white, while the breast, belly and undertail coverts are off-white, or very faintly fringed pale buff on the flanks. Wings and tail are slightly darker brown than rufescens.

Colours of soft parts at time of collecting Iris chestnut, legs and feet grey-brown, bill light brown with a paler lower mandible.

Measurements of type Wing (flattened) 74 mm, tail 66 mm, culmen from base of skull 23 mm, tarsus 29 mm, weight 19.5 gms at time of collecting.

Breeding and distribution As this reed warbler appeared almost impossible to secure with mist-nets GDM decided to lure them out of their recess by using a tape recording made of the nominate form in Niceria. The reaction to the tape was remarkably swift, although GDM soon discovered that the size of the population was rather small in comparison with λ . bacticatus (which is evidently numerous at Lake Guiers). Judging from the response, one pair was found in about every 0.5-1 ha of Typha beds. The female collected on 26 April was in breeding condition with an enlarged ovary

Table 1 Measurements of Acrocephalus rufescens senegalensis and A. r. rufescens

	A. r. senegalensis		A. r. rufescens	
	5 males	2 females	10 males	10 females
Wing	74-75 (74.6)	73, 74 (73.5)	69-76 (73.4)	66-73 (70.1)
Tail	68-72 (70.2)	65, 66 (65.5)	64-72 (67.7)	61-69 (65.4)
Bill	21.5-23 (22.1)	21, 23 (22)	20-23 (22.4)	21-22 (21.5)
Tarsus	28-29 (28.4)	27, 29 (28)	28-30 (29.3)	27-39 (28.2)
Weight	20-21 (20.4)	19.5, 23 (21.25)		-

Means in parenthesis.

(ovules to 3 mm) and the five males taken between 24 and 26 April had enlarged conads (4-5 mm), so that the species would appear to have a breeding regime similar to that of A. bacticatus, which also breeds there in May-June and like that species, April adults show some degree of wear to their plumage. In West Africa only two localities for A. rufescens are shown in Hall and Moreau's Atlas (1970): Lake Guiers, and near Dakar (R. de Naurois, pers. comm.). The Atlas does not show any other records west of 0° along the coast or between Chad and Senegal, and to the best of our knowledge there is only one other record, of a bird caught along the Niger in Mimosa pigra at Bamako in November (Lamarche 1981).
